

A Device for Protecting Medical Apparatus

ABSTRACT.

A device for protecting medical apparatus from contamination by infectious agents comprises a containment body having an inlet (5) 5 destined to be set in fluid communication with an extracorporeal circuit (3) of blood, and an outlet (6) destined to be connected to a fluid line operatively connected to a pressure gauge of a medical apparatus (4). The inlet (5) is in gas communication with the outlet (6) across an internal cavity (11) of the containment body. Two hydrophobic 10 membranes (12, 13) are predisposed in the containment body between the inlet (5) and the outlet (6). The membranes (12, 13) each define an anticontamination barrier which is gas-permeable. The device transmits the pressure of the extracorporeal circuit to the pressure gauge, with no relevant loss of head, while at the same time protecting, with a high 15 degree of security, the medical apparatus (4) from risks of contamination by pathogens originating in the extracorporeal circuit.
